Overview

- Stochastic local volatility (SLV) models, including:
  - SABR (variants: shifted, lambda, Heston, etc.)
  - Quadratic SLV (Lipton), root quadratic SLV
- Includes pure stochastic volatility (SV) as special case:
  - Heston, Jacobi, Hull-White, 3/2, Stein-Stein, 4/2, Scott, \( \alpha \)-Hypergeometric, etc.
- Includes mean-reverting Commodity models:
  - Ornstein-Uhlenbeck with SV, mean-reverting SABR, etc.
- Contracts: European, Bermudan/American, Barrier, Asian, Parisian/Occupation time, Lookback
Stochastic Local Volatility

- Local volatility (Dupire (1994)\textsuperscript{4}, Derman et al (1996)\textsuperscript{5}), for “perfect calibration”:

\[ LV : \quad dS_t = S_t \mu dt + \sigma_{LV}(S_t, t)S_t dW_t \]

- Stochastic volatility for realistic surface dynamics:

\[ SV : \quad \begin{cases} 
    dS_t = S_t \mu dt + m(v_t)S_t dW_t^{(1)}, \\
    dv_t = \mu(v_t)dt + \sigma(v_t)dW_t^{(2)} 
\end{cases} \]

- Stochastic local volatility to unite the two:

\[ SLV : \quad \begin{cases} 
    dS_t = \omega(S_t, v_t)dt + m(v_t)\Gamma(S_t)dW_t^{(1)}, \\
    dv_t = \mu(v_t)dt + \sigma(v_t)dW_t^{(2)} 
\end{cases} \]

Table: Dynamics and variance transforms for some stochastic volatility models.
Technical Assumptions

- **Assumption 1.** Let \( P_t \Phi(S, \nu) = \mathbb{E}[\Phi(S_t, \nu_t)|S_0 = S, \nu_0 = \nu] \), and for any \( \Phi \in C_0([0, \infty) \times [0, \infty)) \), we assume that \((S_t, \nu_t)\) is a Feller process, i.e.
  - \( P_t \Phi \in C_0([0, \infty) \times [0, \infty)) \) for any \( t \geq 0 \)
  - \( \lim_{t \to 0} P_t \Phi(S, \nu) = \Phi(S, \nu) \) for any \((S, \nu) \in [0, \infty) \times [0, \infty)\).

  The Feller property guarantees that there exists a version of the process \((S_t, \nu_t)\) with cádlág paths satisfying the strong Markov property.

  The family of \( P_t \Phi(S, \nu) \) is determined by its infinitesimal generator \( \mathcal{L}^S \):

  \[
  \mathcal{L}^S \Phi(S, \nu) = \lim_{t \to 0^+} \frac{(P_t \Phi - \Phi)(S, \nu)}{t}.
  \]  

- **Assumption 2.** We assume that

  \[
  \lim_{(S, \nu) \to (0, 0)} \mathcal{L}^S \Phi(S, \nu) = 0.
  \]
SLV Methodology Outline

\[
\text{SLV: } \begin{cases} 
    dS_t = \omega(S_t, v_t)dt + m(v_t)\Gamma(S_t)dW_t^{(1)}, \\
    dv_t = \mu(v_t)dt + \sigma(v_t)dW_t^{(2)}
\end{cases}
\]

1. Transformation: \((S_t, v_t) \rightarrow (X_t, v_t)\), to decouple the local and stochastic volatility term \(m(v_t)\Gamma(S_t)\)

2. First layer approximation: \((\tilde{X}_t, v_{\alpha(t)})\), where \(v_{\alpha(t)}\) is a locally consistent CTMC approximation to \(v_t\).

3. Second layer approximation: \((\tilde{X}_t^{(N)}, v_{\alpha(t)})\), a nonlinear Regime Switching CTMC

4. Dimension Reduction: \((\tilde{X}_t^{(N)}, v_{\alpha(t)}) \rightarrow Y_t\), a one-dimensional CTMC

5. Pricing in the space of \(Y_t\)
Transformed Process

- First apply standard Cholesky decomposition

\[
dS_t = \omega(S_t, \nu_t)dt + m(\nu_t)\Gamma(S_t)dW_t^{(1)}
\]

\[
= \omega(S_t, \nu_t)dt + m(\nu_t)\Gamma(S_t)(\rho dW_t^{(2)} + \sqrt{1 - \rho^2} dW_t^{(*)})
\]

which contains two (independent) Brownian motions

- Goal is to obtain an auxiliary process of the form:

\[
dF(S_t, \nu_t) = F^1(S_t, \nu_t)dt + F^2(S_t, \nu_t)dW_t^{(*)}
\]

driven by a single Brownian motion

- Such a process is amenable to a regime switching approximation
Recall: \( dS_t = \omega(S_t, v_t)dt + m(v_t)\Gamma(S_t)dW^{(1)}_t \)

Lemma

Define the functions \( g(x) := \int_x^\infty \frac{1}{\Gamma(u)} du \) and \( f(x) := \int_x^\infty \frac{m(u)}{\sigma(u)} du \).

Then we have

\[
\begin{cases}
    d(g(S_t) - \rho f(v_t)) = \left( \frac{\omega(S_t, v_t)}{\Gamma(S_t)} - \frac{\Gamma'(S_t)}{2} m^2(v_t) - \rho h(v_t) \right) dt \\
    + \sqrt{1 - \rho^2} m(v_t) dW^*_t,
\end{cases}
\]

\( dv_t = \mu(v_t) dt + \sigma(v_t) dW^{(2)}_t, \)

where \( W^*_t \) and \( W^{(2)}_t \) are two independent Brownian motions, and

\[ h(v_t) = \mu(v_t) \frac{m(v_t)}{\sigma(v_t)} + \frac{1}{2} \left( \sigma(v_t) m'(v_t) - m(v_t) \right). \]

This defines the auxiliary process \( X_t := g(S_t) - \rho f(v_t). \)
Consider a CTMC, \( \alpha(t) \in \mathcal{M} := \{1, 2, \ldots, m_0\} \)

Transition density at time \( t \) of \( \alpha(t + \Delta t)|\alpha(s), 0 \leq s \leq t \), depends only on \( \alpha(t) \)

Dynamics of \( \alpha(t) \) captured by rate matrix \( \Lambda = [\lambda_{ij}]_{m_0 \times m_0} \)

\( \lambda_{ij} \) is transition rate from state \( i \) to \( j \), and \( \lambda_{ii} = -\sum_{j \neq i} \lambda_{ij} \)

In particular, \( \forall i \neq j : \)

\[
Q(\alpha(t + \Delta t) = j|\alpha(t) = i, \alpha(t'), 0 \leq t' \leq t) = \lambda_{ij} \Delta t + o(\Delta t).
\]

Closed-form probabilities in terms of matrix exponential:

\[
P(\Delta t) = \exp(\Lambda \cdot \Delta t) := \sum_{k=0}^{\infty} \frac{(\Lambda \cdot \Delta t)^k}{k!}
\]
First Layer Approximation: Variance CTMC Approximation

- Define $v_{\alpha(t)}$, a CTMC approximating $v_t$, by defining a rate matrix $\Lambda = [\lambda_{ij}]_{m_0 \times m_0}$ for $\alpha(t)$

- Local consistency: choose $\Lambda$ so that first two moments of $dv_t$ and $dv_{\alpha(t)}$ match locally

- For example: uniform grid $v_i = v_1 + \delta_v(i - 1)$, $i = 1, \ldots, m_0$

\[
\begin{align*}
\lambda_{ij} &= \begin{cases} 
-\frac{\mu(v_i)}{2\delta_v} + \frac{\sigma^2(v_i)}{2\delta_v^2}, & j = i - 1, \\
- \frac{\sigma^2(v_i)}{\delta_v^2}, & j = i, \\
\frac{\mu(v_i)}{2\delta_v} + \frac{\sigma^2(v_i)}{2\delta_v^2}, & j = i + 1
\end{cases}
\end{align*}
\]

- In practice, we apply the generator of Lo and Skindilias (2014), as in Kirkby et. al (2016) for pure SV, combined with nonuniform grid of Tavella and Randall (2000)
In first stage, we approximated $v_t$ with $v_{\alpha(t)}$

Process $(\tilde{X}_t, v_{\alpha(t)})$ defines a nonlinear regime switching (RS) model, which maps to $(\tilde{S}_t, v_{\alpha(t)})$

Mapping is defined by

$$\tilde{X}_t := g(\tilde{S}_t) - \rho f(v_{\alpha(t)})$$

$$\tilde{S}_t = g^{-1}(\tilde{X}_t + \rho f(v_{\alpha(t)}))$$

In particular, we have a new RS model for $\tilde{S}_t$,

$$d\tilde{S}_t = \omega(\tilde{S}_t, v_{\alpha(t)})dt + m(v_{\alpha(t)})\Gamma(\tilde{S}_t)dW_t^{(1)}$$

$\tilde{S}_0 = S_0$
Second Layer Approximation: Regime Switching CTMC

- We focus on the dynamics of $\tilde{X}_t$, with solution:

$$\tilde{X}_t = g(S_0) - \rho f(v_0) + \int_0^t \theta(\tilde{X}_t, v_{\alpha(t)}) dt + \sqrt{1 - \rho^2} \int_0^t m(v_{\alpha(t)}) dW_t^*$$

- For each fixed state $v_{\alpha(t)}$, this process is a (time-homogeneous) diffusion.

- Hence, we apply a second layer CTMC, with generators $G^l = [q^l_{ij}]_{N \times N}$, for $l = 1, \ldots, m_0$:

$$q^l_{kj} = \begin{cases} 
-\frac{\theta(x_k, v_l)}{2\delta_x} + \frac{\tilde{\sigma}^2(v_i)}{2\delta_x^2}, & j = k - 1, \\
- \frac{\tilde{\sigma}^2(v_i)}{\delta^2_x}, & j = k, \\
\frac{\theta(x_k, v_l)}{2\delta_x} + \frac{\tilde{\sigma}^2(v_i)}{2\delta_x^2}, & j = k + 1
\end{cases}$$

where $\tilde{\sigma}(v_l) := \sqrt{1 - \rho^2} m(v_l)$.

- New process: $(\tilde{X}^{(N)}, v_{\alpha(t)})$ is a RS-CTMC.
Relation to Infinitesimal Generator

- The infinitesimal generator of \((\tilde{X}^{(N)}, v_\alpha(t))\):

\[
\mathcal{L}_N^{m_0} V(x_k, v_l) = \sum_{j=1}^{N} g_{kj}^l V_j^l + \sum_{n=1}^{m_0} \lambda_{ln} V_k^n \\
= \left( g_{k,k-1}^l V_{k-1}^l + g_{kk}^l V_k^l + g_{k,k+1}^l V_{k+1}^l \right) \\
+ \left( \lambda_{l,l-1} V_{k-1}^l + \lambda_{ll} V_k^l + \lambda_{l,l+1} V_{k+1}^l \right) .
\]

- Generator of \((X_t, v_t)\) given by

\[
\mathcal{L} V(x, v) = \frac{1}{2} (1 - \rho^2)[m(v)]^2 \frac{\partial^2 V}{\partial x^2} + \theta(x, v) \frac{\partial V}{\partial x} \\
+ \frac{1}{2} \sigma^2(v) \frac{\partial^2 V}{\partial v^2} + \mu(v) \frac{\partial V}{\partial v} .
\]
Relation to Infinitesimal Generator

- Comparing, for example, the underlined terms:

$$\lambda_{l,l-1} V_{k-1}^l + \lambda_{ll} V_k^l + \lambda_{l,l+1} V_{k+1}^l$$

$$= \frac{\sigma^2(v_l)}{2} \left[ \frac{V_{k-1}^l - 2V_k^l + V_{k+1}^l}{\delta_v^2} \right] + \mu(v_l) \left[ \frac{V_{k+1}^l - V_{k-1}^l}{2\delta_v} \right]$$

$$\rightarrow \frac{1}{2} \sigma^2(v_l) \frac{\partial^2 V}{\partial v^2} + \mu(v_l) \frac{\partial V}{\partial v}, \quad \text{as } \delta_v \downarrow 0$$

- Analogous result for other terms as $$\delta_x \downarrow 0$$

- Hence weak convergence: $$(\tilde{X}^{(N)}(t), v_{\alpha(t)}) \Rightarrow (X_t, v_t),$$ from which expected values (prices) converge to true values
Weak Convergence

Proposition

(Proposition 3) For each fixed \(m_0\) and \(N\), let \([x_1, x_N]\) and \([\nu_1, \nu_{m_0}]\) be the truncation domains\(^6\) for the processes \(\tilde{X}_t^{(N)}\) and \(\nu_{\alpha(t)}^{m_0} \equiv \nu_{\alpha(t)}\) respectively. For each \(m_0\) and \(N\), choose \(\Lambda = (\lambda_{ij})_{m_0 \times m_0}\) and \(G_l = (q_{ij}^l)_{N \times N}\) for \(l = 1, \ldots, m_0\) as in the paper. Then

\[
(\tilde{X}_t^{(N)}, \nu_{\alpha(t)}^{m_0}) \xrightarrow{\text{w}} (X_t, \nu_t), \quad \text{as} \quad m_0, N \to \infty.
\]

Here \(\xrightarrow{\text{w}}\) indicates weak convergence of the regime-switching CTMC approximation to the true process.

\(^6\)We have the freedom to choose \(x_1, x_N, \nu_1, \nu_{m_0}\), and we will choose them so that the domain of \((X_t, \nu_t)\) is covered sufficiently.
Convergence Order

- Li and Zhang (2016)\(^7\) consider an error estimate of the option value using the Markov chain approximation of Mijatovic and Pistorius (2013)\(^8\).

- Using the spectral analysis, they show that for call/put-type payoffs, the convergence is of second order, while for digital-type payoffs, the convergence is only of first order in general.

- It is expected that the same convergence type would hold for the model considered in this paper. It would be very interesting to carry this out. We leave this as an interesting project for future studies.

---

Transform to One-dimensional CTMC

- Process \((\tilde{X}^{(N)}, \nu_{\alpha(t)})\) defines a RS-CTMC
- Next apply theorem of Song et al (2016)\(^9\) to convert to a 1-D CTMC, \(\{Y_t, t \geq 0\}\), on \(S_Y := \{1, 2, \ldots, N \cdot m_0\}\)
- First find a bijection between state space \(S_X \times M\) of \((\tilde{X}^{(N)}, \nu_{\alpha(t)})\) to \(S_Y\) of \(Y_t\)
- Define the mapping \(\phi : S_X \times M \to S_Y\) by
  \[
  \phi(x_k, l) = (l - 1)N + k, \quad 1 \leq l \leq m_0, \ 1 \leq k \leq N
  \]
- Inverse \(\phi^{-1} : S_Y \to S_X \times M\) by
  \[
  \phi^{-1}(n) = (x_k, l), \quad \text{for } n \in S_Y
  \]
  where \(k\) is the unique integer satisfying \(n = (l - 1)N + k\) for some \(l \in \{1, 2, \ldots, m_0\}\).

Transform to One-dimensional CTMC

Theorem

(Song et al (2016)) Define the $N \cdot m_0 \times N \cdot m_0$ rate matrix

$$G = \begin{pmatrix}
\lambda_{11}I_N + G_1 & \lambda_{12}I_N & \cdots & \lambda_{1m_0}I_N \\
\lambda_{21}I_N & \lambda_{22}I_N + G_2 & \cdots & \lambda_{2m_0}I_N \\
\vdots & \vdots & \ddots & \vdots \\
\lambda_{m_01}I_N & \lambda_{m_02}I_N & \cdots & \lambda_{m_0m_0}I_N + G_{m_0}
\end{pmatrix},$$

where $I_N$ is the $N \times N$ identity matrix, $G_l = (q_{kj})_{N \times N}$, and

$\Lambda = (\lambda_{k,j})_{m_0 \times m_0}$. Then we have

$$\mathbb{E}\left[\psi(\tilde{X}^{(N)}, \alpha)|\alpha(0) = i, \tilde{X}_0^{(N)} = x_k\right]$$

$$= \mathbb{E}[\psi \circ \phi^{-1}(Y)|Y_0 = (i - 1)N + k],$$

for any path-dependent payoff function $\psi$. Here we have defined

$\tilde{X}^{(N)} := (\tilde{X}_t^{(N)})_{0 \leq t \leq T}$, $\alpha := (\alpha(t))_{0 \leq t \leq T}$, and $Y := (Y_t)_{0 \leq t \leq T}$.
European Options

- Vanilla option prices for the underlying $S_T$ can now be approximated with respect to $\tilde{S}_T^{(N)} := g^{-1}(\tilde{X}_T^{(N)} + \rho f(v_{\alpha(T)})).$ (3)

- For example

$$\mathbb{E}\left[e^{-rT} (S_T - K)^+ \right| v_0, S_0]$$

$$\approx \mathbb{E}\left[e^{-rT} \left(\tilde{S}_T^{(N)} - K\right)^+ \right| \alpha(0) = i, \tilde{X}_0^{(N)} = x_k]$$

$$= e^{-rT} \cdot e_{i,x_k} \cdot \exp(G T) \cdot H^{(1)}$$

where $e_{i,x_k}$ is a $1 \times Nm_0$ vector with all entries equal to 0 except that the $(i - 1)N + k$ entry is equal to 1, and $H^{(1)}$ is an $Nm_0 \times 1$ vector with

$$H^{(1)}_{(l-1)N+j} = \begin{cases} 
(g^{-1}(\tilde{x}_j + \rho f(v_l)) - K)^+ & \text{for a call,} \\
(K - g^{-1}(\tilde{x}_j + \rho f(v_l)))^+ & \text{for a put.}
\end{cases}$$
By the continuity of $g^{-1}(\cdot)$, it follows from Proposition 3 and the continuous mapping theorem that

$$\tilde{S}_T^{(N)} \Longrightarrow S_T, \quad \text{as} \quad m_0, N \to \infty,$$

It then follows that $\mathbb{E}[H(\tilde{S}_T^{(N)})] \to \mathbb{E}[H(S_T)]$ for any bounded payoff $H(\cdot)$ which is continuous on $C \subset [0, \infty)$ such that $\mathbb{Q}[S_T \in C] = 1$.

Assuming that $\mathbb{E}[H(S_T)] < \infty$, for any $\epsilon > 0$ we can choose $\theta > 0$ such that $\mathbb{E}[H(S_T) - H(S_T)1_{\{S_T \leq \theta\}}] < \epsilon$, and

$$\mathbb{E} \left[ H(\tilde{S}_T^{(N)})1_{\{S_T^{(N)} \leq \theta\}} \right] \to \mathbb{E} \left[ H(S_T)1_{\{S_T \leq \theta\}} \right].$$

Hence, the Markov chain value approximation will converge for any finitely valued European option.
American and Barrier Options

- Define transition density \( P_Y(\Delta) := \exp(G\Delta) \) of \( Y_\Delta \).
- Bermudan value recursion for \( V^{Ber}(\tilde{X}_0^{(N)}, \alpha_0, K) = V_0(n) \):

\[
\begin{align*}
V_M &= H^{(1)} \\
V_m &= \max\{e^{-r\Delta}P_Y(\Delta)V_{m+1}, H^{(1)}\}, \quad m = M - 1, \ldots, 0
\end{align*}
\]

- Barrier option with knock-out barrier \( B \geq 0 \): define the indicator vector \( 1_B \), where for each \( n = (l - 1)N + k \in S_Y \),

\[
1_B(n) = \begin{cases} 
\mathbb{1}\{g(B) \leq x_k + \rho f(v_l)\}, & \text{down-and-out} \\
\mathbb{1}\{g(B) \geq x_k + \rho f(v_l)\}, & \text{up-and-out,}
\end{cases}
\]

- Recursion to find \( V^{Bar}(\tilde{X}_0^{(N)}, \alpha_0, B, K) = V_0(n) \)

\[
\begin{align*}
V_M &= H^{(1)} \circ 1_B \\
V_m &= e^{-r\Delta}P_Y(\Delta)V_{m+1} \circ 1_B, \quad m = M - 1, \ldots, 0
\end{align*}
\]
For discretely monitored Asian option

\[
\sum_{m=0}^{M} \tilde{S}_{t_m}^{(N)} = \sum_{m=0}^{M} g^{-1}(\tilde{X}_{t_m}^{(N)} + \rho f(v_{t_m}))
\]

\[
= \sum_{m=0}^{M} \zeta \circ \phi^{-1}(Y_{t_m}) = \sum_{m=0}^{M} h(Y_{t_m}) := \tilde{B}_{M}^{(N)}.
\]

Let \( v_d(M, k) = \mathbb{E}_{i,x_k}[(k - \tilde{B}_{M}^{(N)})^+] \), then

\[
V_d(M, K) = \frac{e^{-rT}}{M+1} v_d(M, (M+1)K)
\]

which is found upon inverting the Laplace transform:

\[
\int_{0}^{\infty} e^{-\theta k} v_d(M, k) dk = \frac{e_{i,x_k} \cdot (e^{-\theta D} P(\Delta))^M e^{-\theta D} \cdot 1}{\theta^2}.
\]
Occupation Time Derivatives

- Define continuous and discrete occupation time for barrier \( L \):
  \[
  \tau_T(L) := \int_0^T \mathbf{1}\{S_u \leq L\} \, du, \quad \tau_M(L) := \sum_{m=0}^M \mathbf{1}\{S_{t_m} \leq L\}
  \]

- Value of proportional payoff (with \( \rho \geq 0 \)):
  \[
  C_c(\kappa, T) = e^{-rT} \mathbb{E}[e^{-\rho \tau_T(L)}(S_T - e^{-\kappa})^+].
  \]

- Closed-form approximation of Laplace Transform:
  \[
  \int_{-\infty}^{\infty} e^{-\phi \kappa} C_c(\kappa, T) \, d\kappa \approx \frac{e^{-rT}}{\phi(1 + \phi)} \mathbf{e}_{i,x_k} \cdot e^{(\mathbf{G} - \mathbf{\tilde{D}})T} \tilde{V}_\phi(\mathbf{y}), \quad (4)
  \]

- (Note): \( \tilde{V}_\phi(\cdot) := (\zeta \circ \phi^{-1}(\cdot))^{1+\phi} \), \( \mathbf{y} := (1, 2, \ldots, N \cdot m_0)^T \),

  and \( \tilde{\mathbf{D}} = (\tilde{d}_{nn})_{Nm_0 \times Nm_0} \) is a diagonal matrix

  \[
  \tilde{d}_{nn} = \tilde{H}(n) = \rho \cdot \mathbf{1}\{\zeta \circ \phi^{-1}(n) \leq L\} \quad \text{for} \quad n \in S_Y
  \]
By the continuity of $g^{-1}(\cdot)$, it follows from Proposition 3 and the continuous mapping theorem that

$$\tilde{\mathcal{S}}_T^{(N)} \xrightarrow{} S_T, \quad \text{as} \quad m_0, N \to \infty,$$

Again by the continuous mapping theorem we have

$$h(\tilde{\mathcal{S}}_{t_m}^{(N)}) \xrightarrow{} h(S_{t_m}), \quad \text{for any continuous function} \quad h.$$

Hence the Theorem 9 of Song et al. (2013)$^{10}$ implies that value of discretely monitored barrier/Bermudan/Asian options written on $h(\tilde{\mathcal{S}}_{t_m}^{(N)})$ will converge to those written on $h(S_{t_m})$.

---

Recall the classical SABR model of Hagan et al (2002)\(^\text{11}\):

\[
\begin{align*}
    dS_t &= v_t S_t^\beta \, dW_t^{(1)}, \\
    dv_t &= \alpha v_t \, dW_t^{(2)},
\end{align*}
\]

Combines CEV local volatility \(S_t^\beta\) with GBM volatility process

Auxiliary process:

\[\tilde{X}_t := g(\tilde{S}_t) - \rho f(v_{\alpha(t)}) = (\tilde{S}_t)^{1-\beta}/(1 - \beta) - \rho v_{\alpha(t)}/\alpha,\]

Dynamics

\[
d\tilde{X}_t = \left( -\frac{\beta}{2(1 - \beta)} \frac{v_{\alpha(t)}^2}{(\tilde{X}_t + \rho v_{\alpha(t)}/\alpha)} \right) dt + \sqrt{1 - \rho^2 v_{\alpha(t)}} \, dW_t^* \]

Extensions

- Given a local volatility component $\Gamma(S_t)$, we can "mix-and-match" our favorite variance processes to improve calibration in targeted markets.

- E.g. variations of SABR include Heston-SABR, $\lambda$-SABR, etc., and many more variance dynamics can be applied.

- Moreover, as long as the Lamperti transform $g(S_t)$ can be derived, monotonicity guarantees the existence of $g^{-1}(\cdot)$.

- Hence, even if $g^{-1}(\cdot)$ is not available in closed form, we can easily invert numerically for the required values along our grid.
